

3.8 User Library

The User Library contains a collection of functions that you can define based on the requirements. Create a User Library file on the PC and upload the file to the controller, and then you can call the user-defined functions in every project.

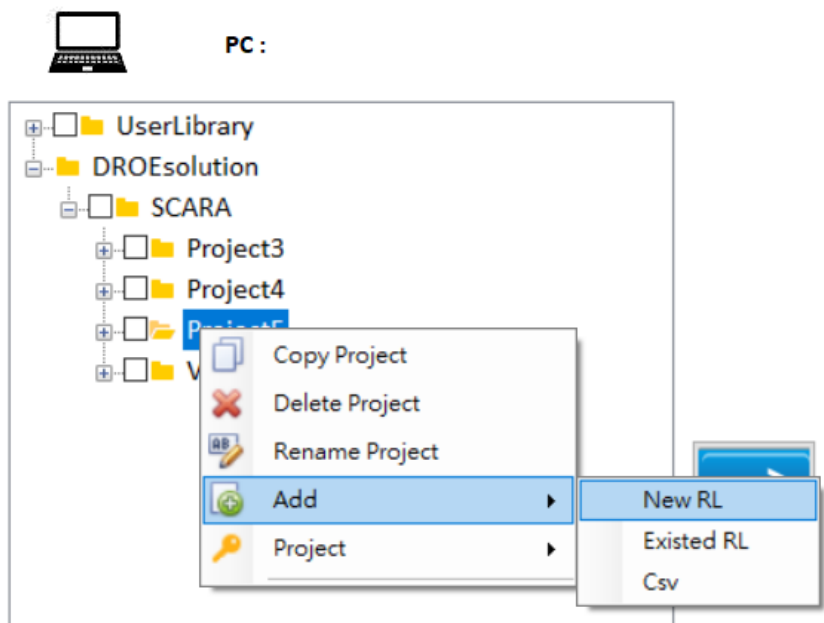

Important:

- You need to upload the User Library file to the controller before calling the user-defined functions.
- When a function in the User Library shares the same name with a function in the main program or a built-in instruction of the controller, the priority of execution would be: main program function > User Library function > controller's built-in instruction.
- When multiple functions in the User Library share the same name, the system only executes the last loaded function.

How to add a User Library file

1. Right-click the PC project (Project5 as the example). Click **Add** → **New RL** to create a User Library file (.lua).

Note: do not name the User Library file as **main** or include any symbols or spaces, otherwise the file cannot be uploaded to the controller.

2. Write the user-defined functions in the User Library file. In this case, you can only call these self-defined functions in Project5.
